## FOREWORD

The tests described herein were conducted under NASA Apollo contract NAS 9-150, during the period from May 29 to June 4, 1962.

This report was prepared by C. L. Berthold & G. B. Henrich of the Wind Tunnel Projects Group, Los Angeles Division of North American Aviation, Inc.

~~CONFIDENTIAL~~

### ABSTRACT

This report presents dynamic stability data from tests of command module entry and launch escape configurations of a 0.055-scale Apollo model (FD-2) in the low Mach number test section of the Langley Unitary Plan Wind Tunnel. Tests were conducted from 1.60 to 2.75 Mach number and at angles of attack near proposed flight attitudes.

The dynamic stability parameters are presented as standard NASA coefficients in both tabular and plotted form for all configurations tested. In addition, tunnel operating conditions, configuration description, computation equations, tabulated data identification key, and typical schlieren photographs are included.

This report presents basic wind tunnel test data only, in order to make the test results available at the earliest possible date. Analyses and summary of results will be reported later under separate cover.

## I. INTRODUCTION

Dynamic stability tests were conducted on 0.055-scale Apollo (FD-2) models in the low speed test section of the Langley Unitary Plan Wind Tunnel from May 29 to June 4, 1962. Dynamic stability parameters were obtained for the command module entry and launch escape configurations with oscillation in pitch and for the command module entry configuration only, with oscillation in yaw.

Tests were conducted at Mach numbers of 1.60, 1.80, 2.00, 2.50, and 2.75 to fill in the Mach number range not covered in two previous tests on this model (Ref. a & b). A more current Launch Escape configuration was tested with and without a disc near the rocket base. The basic configurations were run at two stagnation pressures to obtain the effect of Reynolds number variation. Reynolds numbers, based on the maximum diameter of the model, varied from  $0.628 \times 10^6$  to  $3.98 \times 10^6$ . All dynamic stability derivatives were measured during forced oscillation of the model in pitch or yaw over an amplitude of approximately  $\pm 2^\circ$  about the oscillation center.

~~CONFIDENTIAL~~

## II. REMARKS

This test was performed to investigate the dynamic stability characteristics of the 0.055-scale Apollo (FD-2) models in the Mach number range 1.60 - 2.75, using models, equipment, and methods of obtaining data similar to that described for two previous tests (Ref. a & b), which covered the Mach number range of 2.40 - 4.65 and 0.30 - 1.20, respectively.

Several techniques are currently available for measuring dynamic stability derivatives of models in wind tunnels. This test was performed utilizing what has been termed the inexorable method in which the model is mechanically forced to oscillate in a single degree of freedom at known angular frequency and amplitude while measurements are made of the moment required to sustain the motion.

The support and attached model were forced to perform a constant-amplitude, essentially sinusoidal motion about the oscillation axis by a mechanical scotch yoke and crank arrangement. The crank was connected by a driveshaft to an electric motor mounted in the downstream end of the sting and the drive motor speed was set at various constant values to provide a range of oscillating frequencies. (For maximum accuracy, most test points were recorded at or near the natural frequency of the oscillating model system).

Springs of different stiffness were available to cover a range of resonant frequencies within the range of operating frequencies. These springs were equipped with calibrated strain gages to provide a signal proportional to the displacement.

A stiff strain gage beam, located between the model mounting point and the pivot axis, gave a signal proportional to the moment applied to oscillate the model. It was located so as to be uninfluenced by any friction or mechanical play in the system.

The model was rigidly forced to oscillate with an amplitude of approximately  $\pm 2^\circ$  at known angular frequency and the pivot axis could be rotated  $90^\circ$ , therefore, tests could be made with the model oscillating in pitch or yaw.

By resolving the moment and amplitude functions into orthogonal components the resultant applied moment and displacement and the phase angle between them may be found. With the known oscillation frequency, the aerodynamic-damping and oscillatory-stability moments can be computed.

## II. REMARKS - continued

The tabular and plotted data are presented in Appendices A and B in NASA standard coefficient form referred to the body system of axes originating at the oscillation center. Dynamic stability parameters are utilized to indicate aerodynamic damping-in-pitch ( $C_{m\dot{\alpha}} + C_{m\ddot{\alpha}}$ ), oscillatory longitudinal stability ( $C_{m\alpha} - k^2 C_{m\dot{\alpha}}$ ), and the reduced frequency parameter  $\frac{\omega \ell}{V}$  for tests with oscillations in pitch for the entry, launch escape (3 config.), and command module exit configurations. In addition, coefficients are given for aerodynamic damping-in-yaw ( $C_{n\dot{\beta}} - C_{n\ddot{\beta}} \cos \alpha$ ), oscillatory directional stability ( $C_{n\beta} \cos \alpha + k^2 C_{n\dot{\beta}}$ ) and the reduced frequency parameter  $\frac{\omega \ell}{V}$  for the entry configuration only with oscillations in yaw. The plotted data presents these parameters as a function of angle of attack.

Configurations were tested at Mach numbers ranging from 1.60 to 2.75 and at angles of attack near the proposed flight attitudes. The nominal angle of attack ranges were: Command Module (entry)  $134^\circ$  to  $158^\circ$ ; Command Module (exit) -  $16^\circ$  to  $+8^\circ$ ; Launch Escape Configuration -  $16^\circ$  to  $+8^\circ$ . The majority of data were recorded at nominal  $2^\circ$  increments of set angle of attack throughout these ranges while the model was being rigidly forced to oscillate  $\pm 2^\circ$  in pitch about the set angle. Smaller increments of set angle of attack were used in areas where large changes in stability parameters were observed.

The current Launch Escape Vehicle was tested throughout the standard Mach No. range at two Reynolds Nos. with two configurations; i.e., E35 T15 C2- Rocket Disc Off and E40 T15 C2 - Rocket Disc On. For comparative purposes with previous tests (Ref. a & b), the configuration E4 T12 C2 (Long Tower) was tested at  $M = 1.80$  &  $2.00$  at the maximum Reynolds No.

The command module in entry attitude was run using two different oscillation centers to determine the magnitude of error introduced by such movement. This configuration was also run at two Mach numbers with oscillation in yaw, but the bulk of the test was conducted with oscillation in pitch only.

Any data believed to be affected by shock reflections from the tunnel walls have been deleted from the tabulated sheets and plotted figures. However, because of a malfunction in the angle-of-attack read-out mechanism, the tabulated values of angle of attack for runs 10 through 26 are higher than the nominal angle by as much as  $0.17^\circ$ . For runs 27 and 28, the tabulated angles of attack are low by an equal amount.

~~CONFIDENTIAL~~

### III. MODEL DESCRIPTION

#### A. General

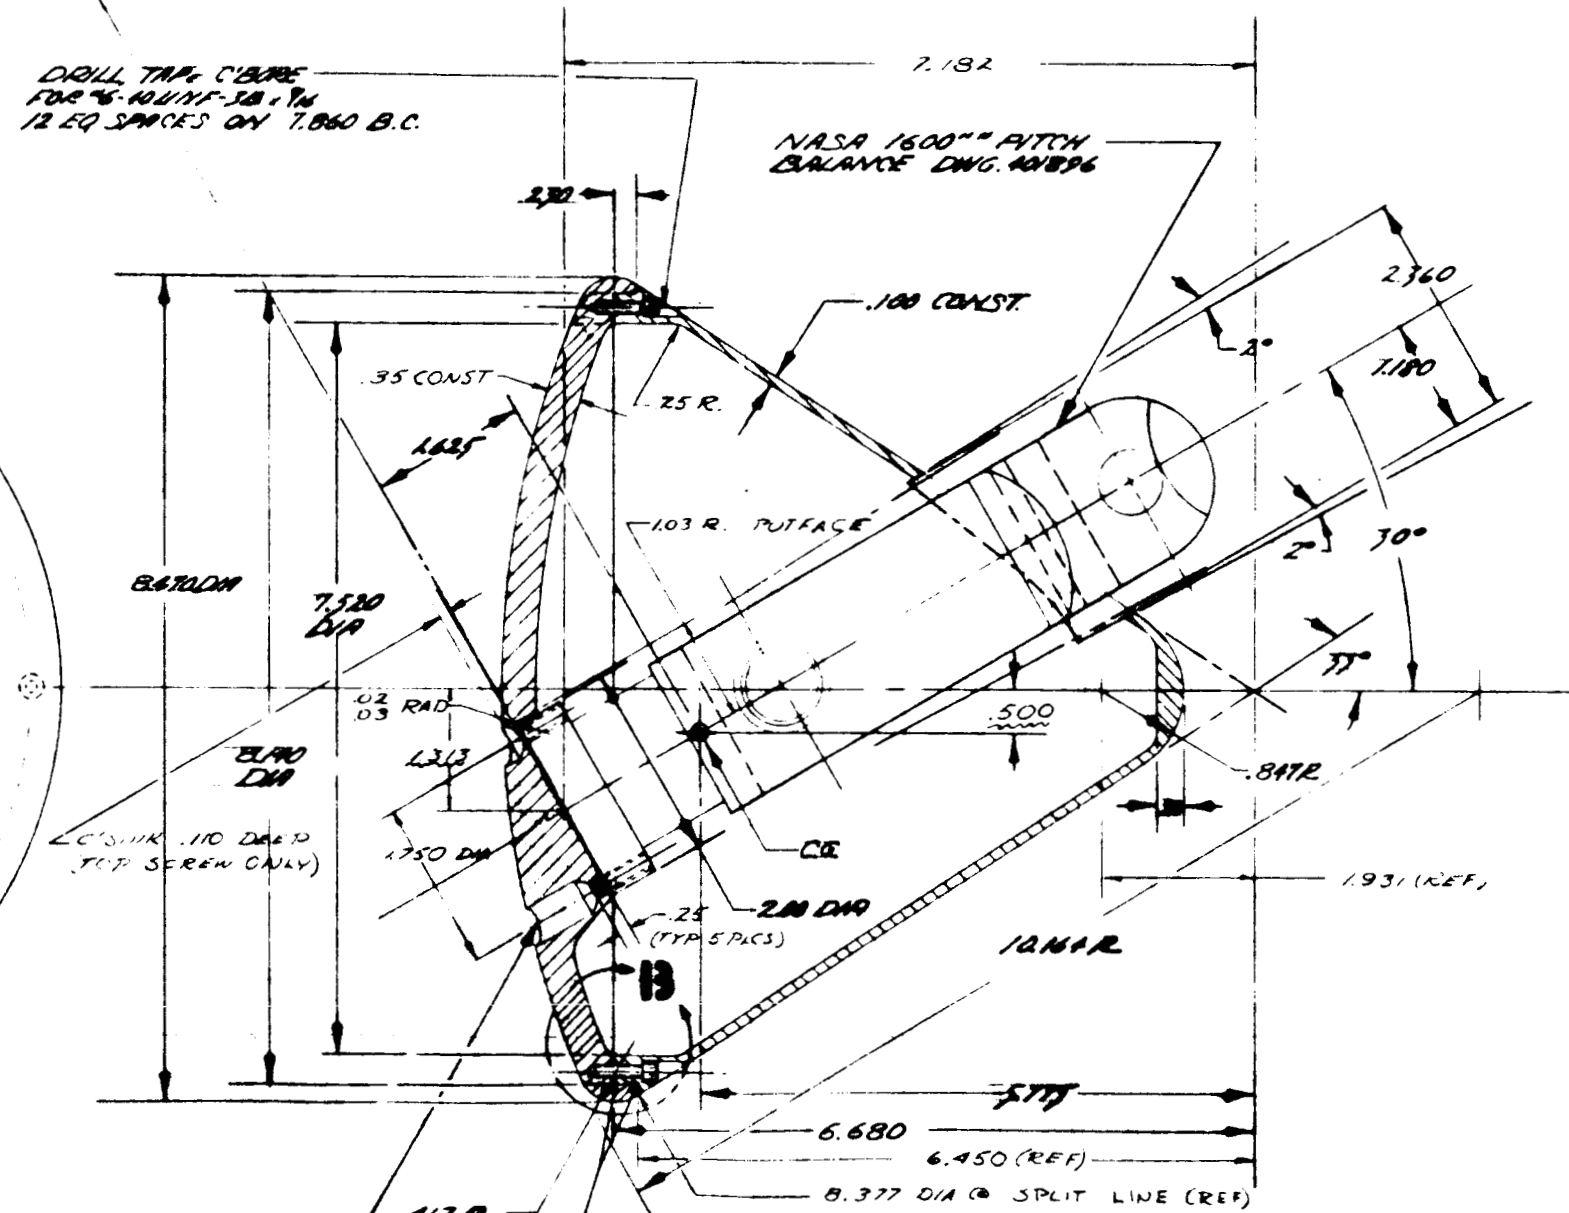

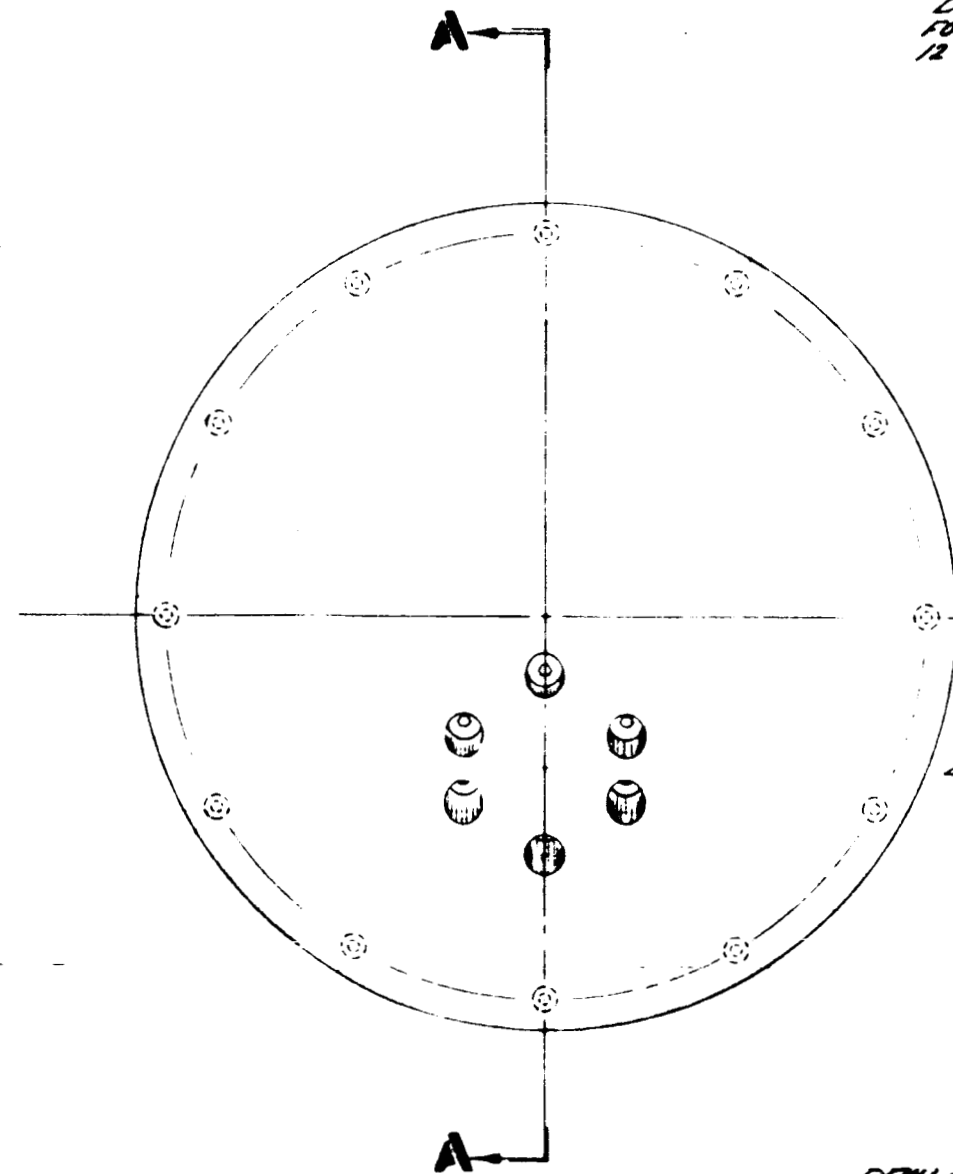

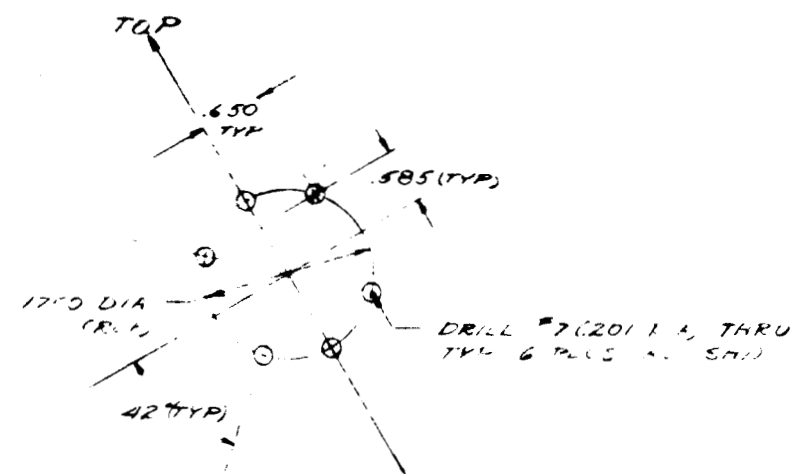

The FD-2 Dynamic Stability Model tested in the low speed test section of the Unitary Plan Wind Tunnel from May 29 to June 4, 1962, was a 0.055-scale representation of the Apollo command module and launch escape vehicle configurations. In addition to the launch escape models used in the two previous programs, a more current launch escape configuration was constructed for these tests.

The configurations tested were aerodynamically smooth for all test conditions. Lightweight materials were utilized in construction of the model, to reduce moment-of-inertia effects, whenever consistent with the structural integrity as established in Reference (c). The command modules were constructed of aluminum alloy (7075-T6), escape tower of Armco steel (17-4 PH SST) and escape rocket of magnesium (QQ-M-31).

The oscillation axis was located as close as possible to the center of gravity of the full scale Apollo vehicle within the physical limits imposed by the model size, chosen to avoid reflected shock waves, and the balance dimensions.

The models were sting mounted with the balance contained within the model to minimize support interference. To allow pitching through angles of attack near the proposed flight attitudes, the models were constructed so that the module axis of symmetry and balance center line formed an angle of  $30^\circ$  for the entry configuration and  $8^\circ$  for the launch escape system.

B. Nomenclature

	<u>Dimensions</u> <u>Full Scale</u>
<u>E<sub>4</sub></u> , Escape Rocket Motor (Dwg. 7121-01058-5)	
Total length (including jettison motor)	248.40 in.
Diameter of Escape Rocket	26.00 in.
Diameter of Escape Rocket Base	47.00 in.
Skirt Flare Angle	30.00°
Nose Cone Half-angle	30.00°
Nose Radius	5.20 in.
Jettison Motor - located aft of rocket motor	
Length of Jettison Motor	69.50 in.
Diameter of Jettison Motor	8.00 in.
Jettison Motor-nozzle exit half angle	17.00°
<u>E<sub>40</sub></u> , Escape Rocket Motor (Dwg. 7121-01061-4)	
Total length	257.28 in.
Diameter of Escape Rocket	26.00 in.
Diameter of Escape Rocket Base	54.60 in.
Skirt Angle Flare	36.92°
Nose Cone Half-angle	15.00°
Nose Radius	2.00 in.
Disc - located forward of skirt flare	
Diameter of Disc	65.00 in.
Disc Thickness	2.27 in.
<u>E<sub>35</sub></u> , Same as "E " except no disc near base of rocket	
<u>T<sub>12</sub></u> , Escape Tower Structure (Dwg. 7121-01058-4)	
Total length	175.00 in.
Number of Longitudinal Members	4
Diameter of Longitudinal Members	2.84 in.
Diameter of Cross Braces	2.29 in.
Distance between attachment points	53.45 in.

## IV. TEST PROCEDURE

A. Test Nomenclature

- A maximum cross-sectional area, sq. ft.,  $\frac{\pi \ell^2}{4}$
- $\ell$  maximum body diameter, ft.
- $q_\infty$  free stream dynamic pressure, lb/sq. ft.
- $\alpha$  angle of attack of model center line, deg. or radians
- $\dot{\alpha}$  rate of change of angle of attack, radians/sec.
- V free stream velocity, ft/sec.
- $\omega$  angular frequency of oscillation, radians/sec.
- k reduced frequency parameter,  $\frac{\omega \ell}{V}$
- R Reynolds number base on  $\ell$
- q angular velocity in pitch, radians/sec.
- $\dot{q}$  rate of change of pitching angular velocity, radians/sec.
- r angular velocity in yaw, radians/sec.
- $\dot{r}$  rate of change of yawing angular velocity, radians/sec.
- $\beta$  angle of sideslip of model center line, radians
- $\dot{\beta}$  rate of change of angle of sideslip, radians/sec.
- $C_m$  pitching-moment coefficient,  $\frac{\text{Pitching Moment}}{q_\infty A \ell}$
- $C_n$  yawing-moment, coefficient,  $\frac{\text{Yawing Moment}}{q_\infty A \ell}$
- I moment of inertia, slug-ft<sup>2</sup>

#### IV. TEST PROCEDURE - continued

##### A. Test Nomenclature - continued

The data presented are referred to the body system of axes and all moments are referred to the intersection of the oscillation axes. Additional coefficients and symbols used in the equations for data reduction are defined as follows:

C — system damping moment, in-lb/radian

K — system spring constant, in-lb/radian

$C_{aero} = C_{run} - C_{tare}$  where  $C_{tare} = \text{constant}$

$(K - I\omega^2)_{aero} = (K - I\omega^2)_{run} - (K - I\omega^2)_{tare}$

For data of type 2 (oscillation in pitch, wingless bodies)

$$C_{mq} + C_m \dot{\alpha} = - \frac{VC_{aero}}{12 q_{\infty} A \ell^2}$$

$$\ell = 0.7058 \text{ ft.}$$

$$C_{m\alpha} - k^2 C_{mq} = - \frac{(K - I\omega^2)_{aero}}{12 q_{\infty} A \ell}$$

$$A = 0.3912 \text{ ft.}^2$$

$$k = \frac{\omega \ell}{V}$$

For data of type 4 (oscillation in yaw, wingless bodies)

$$C_{n_r} - C_{n_{\dot{\beta}}} \cos \alpha = - \frac{VC_{aero}}{12 q_{\infty} A \ell^2}$$

$$C_{n_{\beta}} \cos \alpha + k^2 C_{n_r} = + \frac{(K - I\omega^2)_{aero}}{12 q_{\infty} A \ell}$$

$$k = \frac{\omega \ell}{V}$$

## IV. TEST PROCEDURE - continued

B. Model Installation

The FD-2 model was installed on the NASA 1600 in-lb. dynamic pitch balance (Dwg. 401896) which was mounted on a straight sting containing the oscillating mechanism. The drive motor, clutch resolvers, and frequency generator were all contained in the downstream end of the sting which was stiffened to provide a resonant frequency above the maximum oscillating frequency of the model. The oscillating mechanism was designed to provide maximum stiffness of all drive linkages so that the model responded only to the essentially sinusoidal forcing input of the crank and Scotch yoke.

The models were mounted so that the sting center line and command module axis of symmetry formed an angle of  $30^\circ$  for the entry configuration and  $8^\circ$  for the launch escape configuration to allow testing through angles of attack of  $134^\circ$  to  $158^\circ$  and  $-16^\circ$  to  $+8^\circ$  respectively. The Unitary tunnels basic sting-type support system, which is mounted on a horizontal support strut extending from wall to wall, allowed the model to be traversed across the tunnel to minimize interference from reflected shock waves on the model at higher angles of attack.

## IV. TEST PROCEDURE - continued

C. Instrumentation

The NASA 1600 in.-lb. dynamic pitch balance was used to measure the moment and displacement functions as the model was mechanically forced to oscillate in a single degree of freedom.

In operation of the system, calibrated outputs of the moment and displacement strain gages are passed through coupled electrical sine-cosine resolvers which rotate at the frequency of oscillation. The resolvers transformed the outputs into orthogonal components from which the resultant applied moment and displacement and the phase angle between them were found. With the known oscillation frequency, the aerodynamic-damping and oscillating stability moments were then computed.

All data were computed on a remotely located IBM 7090 computer.

D. Data Reduction Constants

All data was reduced and presented in standard NASA coefficient form referred to the body system of axes originating at the oscillation center.

Reference area =  $A = 0.3912 \text{ ft.}^2$

Reference length =  $\ell = 0.7058 \text{ ft. (Diam.)}$

Q	Dynamic Pressure	Free-stream dynamic pressure lb/ft <sup>2</sup>
V	Velocity	Free-stream velocity ft/sec
RN	Reynolds No.	Reynolds No. $\times 10^{-6}$ based on a a reference length of 0.7058 ft. (This is the maximum diameter of the command module model)

~~CONFIDENTIAL~~

## A. TABULATED DATA FORMAT - continued

<u>Column.</u> <u>Heading</u>	<u>Item</u>	<u>Definition or Remarks</u>
TP	--	Corrected phase angle between driving torque and model displacement. Values near $90^\circ$ and $270^\circ$ indicate velocity resonance.
MACH	Mach No.	Free-stream Mach number
AOS	Angle of Sideslip	Mean angle of sideslip, degrees.
AOA	Angle of Attack	Angle of attack of the model, degrees.
FREQ	Frequency	Frequency of the forced oscillation cycles/sec.
K	Reduced Frequency Parameter	k, see equations
CMQ	$C_{m\dot{q}} + C_{m\dot{\alpha}}$	Damping-in-pitch parameter
CMA	$C_{m\alpha} = k^2 C_{m\dot{q}}$	Oscillatory longitudinal stability parameter
CNR	$C_{n_r} = C_{n\dot{\beta}} \cos \alpha$	Damping-in-yaw parameter
CNB	$C_{n\beta} \cos \alpha + k^2 C_{n_r}$	Oscillatory directional stability parameter

Note: See Test Nomenclature for definition of stability parameters.

~~CONFIDENTIAL~~

## B. RUN INDEX
